

## Nickel North Project has similar geology as Golden Chalice's Langmuir Property

### VTEM airborne survey reveals large conductive bodies for future drill-testing.

Sedex Mining has recently completed an extensive evaluation of its Canadian property portfolio in order to conserve and focus working capital and resources on priority projects, notably the Nickel North Property, 40 km northwest of Timmins, Ontario and the joint-ventured Tannahill Gold Project, 35 km northeast of Kirkland Lake (see Tannahill Project highlights on facing page,) and the joint-ventured Irishman Project (see Klondike Gold's section on the Irishman.

The road-accessible Nickel North Property covers about 200 square km of prospective ground with similar geology as the nearby Langmuir Property where Golden Chalice Resources is continuing to advance a significant nickel discovery made in 2007. The land package has excellent potential to host "Kambalda-style" nickel mineralization similar to that observed in the Kambalda nickel-mining district of Australia. These deposits typically occur in clusters within mafic and ultramafic flows and sills.

A recent VTEM geophysical survey over the Nickel North Property has revealed numerous anomalies that could represent magmatic flow nickel, copper and platinum group metal mineralization or volcanogenic massive sulphide mineralization consisting of copper, zinc and silver. The Company is reviewing and compiling geophysical and geological data in order to plan the next phase of exploration at the property.
